Abstract. The dynamic intra-nuclear localization of MRP RNA, the RNA component of the ribonucleoprotein enzyme RNase MRP, was examined in living cells by the method of fluorescent RNA cytochemistry (Wang, J., L.-G. Cao, Y.-L. Wang, and T. Pederson. 1991. Proc. Natl. Acad. Sci. USA. 88:7391-7395). MRP RNA very rapidly accumulated in nucleoli after nuclear microinjection of normal rat kidney (NRK) epithelial cells. Localization was specifically in the dense fibrillar component of the nucleolus, as revealed by immunocytochemistry with a monoclonal antibody against fibrillarin, a known dense fibrillar component protein, as well as by digital optical sectioning microscopy and 3-D stereo reconstruction. When MRP RNA was injected into the cytoplasm it was not imported into the nucleus. Nuclear microinjection of mutant MRP RNAs revealed that nucleolar localization requires a sequence element (nucleotides 23-62) previously implicated as a binding site for a nucleolar protein, the To antigen. These results demonstrate the dynamic localization of MRP RNA in the nucleus and provide important insights into the nucleolar targeting of MRP RNA.
Materials and Methods

**Plasmids, In Vitro Transcription, and Fluorescent Labeling of RNA**

The methods used in this study were essentially as described previously (Wang et al., 1991) with only minor modifications. Human MRP RNA was transcribed from EcoRI digested plasmid pHMRPMDT1 (kindly provided by T. Kiss and W. Fillipowicz, Friedrich Miescher-Institut) using T3 RNA polymerase (GIBCO-BRL, Gaithersburg, MD). Plasmids encoding mutant MRP RNAs were constructed by either deletion (pHMRPMDT1) or inversion (pHMRPMDT2) of the 40 base-pair AUII fragment (nucleotides 23-62) of the parental plasmid pHMRPMDT1. MRP-1 and MRP-2 RNAs were transcribed from EcoRI digested plasmids pHMRPMDT1 and pHMRPMDT2, respectively, using T3 RNA polymerase.

All RNAs were transcribed from their appropriately digested plasmid DNAs in the presence of 1 mM ATP, CTP, GTP, UTP (Pharmacia LKB Biotechnology, Piscataway, NJ), and 0.1 mM 5-(a-3-aminoallyl)-UTP (Sigma Chem. Co., St. Louis, MO) by T3 RNA polymerase under the conditions described by the supplier. When desired, 2 μM α-[32P]CTP (New England Nuclear Research Products, Boston, MA) was added to the transcription reaction as a tracer. The RNA was recovered by ethanol precipitation and coupled either to tetramethylrhodamine-5-isothiocyanate (TRITC, isomer G; Molecular Probes, Eugene, OR) or fluorescein-5-isothiocyanate (FITC; Molecular Probes as Probes) as previously described (Langer et al., 1981; Agrawal et al., 1986; Wang et al., 1991). After coupling, the fluorochrome-labeled RNA was purified by gel filtration on a 5-ml Bio-Gel P-60 (BioRad, Hercules, CA) column. RNA from the peak column fractions was twice ethanol precipitated, and then resuspended in sterile 5 mM Tris-acetate buffer (pH 7.0) at a concentration of ~50 μg/ml and centrifuged in a 42.2T1 rotor at 25,000 rpm for 30 min to remove any residual precipitate which might complicate microinjection (Beckman Instrs., Fullerton, CA). The integrity of the fluorescein labeled RNA was examined by agarose gel electrophoresis. All RNAs were heat denatured at 75°C and rapidly cooled to room temperature just before microinjection.

**RNP Assembly and Immunoprecipitation**

In vitro transcribed MRP RNA was incubated for 30 min at 30°C followed by an additional 30 min at 0°C in a 50-μl reaction containing 50% (vol/vol) HeLa cell S100 fraction (Patton et al., 1987), 1 mM ATP, 20 μg yeast tRNA, 75 mM KCl, 2.2 mM MgCl2, 0.25 mM dithiothreitol, and 20 mM Hepes (pH 8.0) buffer. Antibody selection from the reaction mixture was performed with the original described human autoimmune reference serum (Reddy et al., 1983; kindly provided by Eng Tan, Scripps Research Institute, La Jolla, CA) prebound to protein A-Sepharose as previously described (Patton et al., 1989). RNA was extracted from the bound fraction after elution and analyzed by denaturing polyacrylamide gel electrophoresis. Other antibody selection experiments were done with a secondary antibody, either fluorescein-conjugated sheep anti-mouse IgG (Sigma Chemical Co.) or rhodamine-conjugated goat anti-human IgG (Pierce, Rockford, IL), and 0.1 mM 5-(3-aminoallyl)-UTP (England Nuclear Research Products, Boston, MA) was added to the coupling reaction mixture after elution and analyzed by denaturing polyacrylamide gel electrophoresis. In vitro transcribed MRP RNA was incubated for 30 min at 30°C followed by washing extensively with PBS containing 1% BSA. After washing extensively with PBS containing 1% BSA, the secondary antibody, either fluorescein-conjugated sheep anti-mouse IgG (Sigma Chemical Co.) or rhodamine-conjugated goat anti-human IgG (Pierce, Rockford, IL), was added and the coverslip was incubated for 2 h at 37°C. The cells were subsequently washed with PBS containing 1% BSA (at room temperature for ~30 min with three changes of buffer) and examined by fluorescence microscopy.

**Fluorescent Microscopy and Image Processing**

All observations were made with a Zeiss Axiosvert-10 inverted fluorescence microscope equipped with a 100×NA 1.30 Neufluor Ph 3 objective, a 40×/NA 1.0 APOCHROMAT objective, and a 40×/NA 0.65 FL/APOCHROMAT Ph2 objective. A 12 V, 100-W quartz-halogen lamp was used as the light source for epi-illumination. Bandpass filters (Zeiss No. 487915 for rhodamine and No. 487917 for fluorescein) were used for fluorescence observations, and no crossover between fluorescein and rhodamine was detectable. Fluorescence images were acquired with a cooled-CCD camera (Star 1; Photometric, Tucson, AZ) linked to a Personal IRIS 4D/20 workstation (Silicon Graphics Inc., Mountain View, CA) and image processor (Series 150; Image Technology, Woburn, MA) for data storage and display. To preserve the geometry of the displayed image, the pixel aspect ratio of the CCD images was converted from 1:1 to 5:4 before input into the image processor which displays images as arrays of rectangular (54) pixels. Typical exposure times were 15 s for both living and fixed cells. To generate superimposed images, paired images were placed into registration by rapidly alternating the display between the two images, while moving one image relative to the other until no wobbling was observed (Cao and Wang, 1990; Cao et al., 1993). Hardcopies of images were generated using a Kodak ColorEase PS printer (Eastman Kodak Company, Rochester, NY).

**Results**

**In Vitro Assembly of Fluorescently Labeled MRP RNA**

Human MRP RNA (Fig. 1) readily associates with a ~40,000-mol wt protein, the To antigen (Yuan et al., 1991), which is present in HeLa cell extracts. The To antigen was initially identified using patient sera containing antibodies directed against MRP RNA-containing ribonucleoprotein particles (Reimer et al., 1983; Kipnis et al., 1990). As shown in Fig. 1, both rhodamine-coupled and noncoupled MRP RNA assembled into a ribonucleoprotein complex immunoselectable by To autoimmune serum. These results show, via direct immunoselection of the fluorescent MRP RNA itself, that it assembles into a ribonucleoprotein complex immunoselectable by To autoimmune serum. Fig. 2B further shows, via direct immunoselection of the fluorescent MRP RNA, that it assembles into a ribonucleoprotein complex with the To antigen but does not associate with fibrillarin, as a negative control. These results establish that, at our level of rhodamine coupling (5-8 rhodamines per MRP RNA molecule), the fluorochrome labeling does not significantly impair the assembly of MRP RNA into the To ribonucleoprotein complex, nor does it induce MRP RNA to spuriously bind other proteins (e.g., fibrillarin).
Figure 1. Human MRP RNA. The secondary structure is that proposed by Schmitt et al. (1993). The solid line represents a single phosphodiester bond linkage between nucleotides 67 and 68. The recognition sequences for AvrII and MspI are indicated.

Localization of Nucleus-microinjected RNase MRP RNA

To examine the movement and localization of the RNA component of RNase MRP in the nucleus, rhodamine-labeled MRP RNA was microinjected into the nuclei of normal rat kidney (NRK) cells (Fig. 3). At the earliest timepoint examined after nuclear microinjection (4 min, Fig. 3 b), most of the rhodamine-labeled MRP RNA was localized in nucleoli. We have consistently observed this strikingly rapid nucleolar localization of MRP RNA. Over time, the amount of nucleus-localized MRP RNA decreased and signal subsequently appeared in both the nucleoplasm and cytoplasm (Fig. 3, b–f). The numerous cytoplasmic foci observed 3 h after nuclear microinjection (Fig. 3, d and f) were highly motile as visualized by time-lapse fluorescence imaging (data not shown). Although we have not further identified these cytoplasmic sites, MRP RNA has been localized in mitochondria by ultrastructural in situ hybridization (Li et al., 1994).

The cell microinjected in Fig. 3 is binucleate. It can be seen that, once in the cytoplasm, the rhodamine-labeled MRP RNA did not enter the other nucleus of this cell (see Fig. 3, d and f), indicating that MRP RNA lacks signals for cytoplasm to nucleus traffic. When rhodamine-labeled MRP RNA was microinjected into the cytoplasm of NRK cells (Fig. 4), we similarly observed the accumulation of signal in numerous cytoplasmic spots which were highly motile (not shown). As can be seen, cytoplasm-microinjected MRP RNA did not enter the nucleus, even after longer incubation times (Fig. 4 b).

The rapidity with which MRP RNA become localized in nucleoli (Fig. 3 b) is striking. To examine even earlier timepoints, cells were fixed with 4% formaldehyde immediately after nuclear microinjection. As shown in Fig. 5, a–e, MRP RNA was predominantly localized in nucleoli as early as 30 s after nuclear microinjection. This extremely fast nucleolar localization of MRP RNA contrasts with our previously described, more gradual movement of microinjected pre-mRNAs to nucleoplasmic sites of accumulation, which takes ~30–60 min (Wang et al., 1991).

Fig. 5 f shows that MRP RNA injected into the cyto-
Figure 3. Localization of human RNase MRP RNA after microinjection into the nucleus of NRK cells. MRP RNA was transcribed in vitro, labeled with rhodamine, purified and microinjected into the nucleus of NRK cells as described in Materials and Methods. The subsequent localization of MRP RNA was visualized in the same living cell at 4 min (b), 25 min (c), and 3 h (d and f). Phase contrast images of the cell at 4 min and 3 h after nuclear microinjection are shown in a and e, respectively. Note that this cell is binucleate (see Results), and that the nuclei have reoriented during the course of observation. We have seen such reorientation in numerous other experiments when the observation period extends to 1–3 h. Bar: (b and e) 5 μm.

plasm is, after 5 min, diffusely distributed. This early, non-localized cytoplasmic distribution is of interest in relation to the punctate cytoplasmic foci seen at later times after cytoplasmic injection (Fig. 4).

Digital Optical Sectioning Microscopy and 3-D Analysis of Nucleolar Localized MRP RNA

Using fluorescence microscopy in combination with digital optical sectioning microscopy, we sought to determine whether the localization of nucleus-microinjected MRP RNA actually occurs throughout the nucleolus or perhaps only on the nucleolar surface. A through-focus series of optical sections (0.25 μm step size) for the same cell observed in Fig. 5 c was obtained (Fig. 6, panel A) and out of focus light was removed by digital image processing (Fig. 6, panel B) as described in Materials and Methods. Analysis of the optical sections through the cell nucleus in Fig. 6 (panels A and B), as well as the three-dimensional stereo pairs generated from these optical sections (panel C), demonstrated that the localized MRP RNA was present throughout the nucleoli in an interlinking network of lobular foci connected by thinner strands, which is the classical organization of the dense fibrillar component as defined.

Figure 4. Localization of MRP RNA after microinjection into the cytoplasm. Rhodamine-labeled MRP RNA was microinjected into the cytoplasm of NRK cells and visualized 16 min (a) or 73 min (b) after microinjection. Bar, 5 μm.
Figure 5. Rapid localization of MRP RNA in subnucleolar structures after nuclear microinjection. NRK cells were nucleus-microinjected with either rhodamine-labeled (a, b, d, and e) or fluorescein-labeled (c) MRP RNA or cytoplasm-microinjected with rhodamine-labeled MRP RNA (f), fixed 30 s (a), 1 min (b), 3 min (c and d), and 5 min (e and f) after microinjection and visualized by fluorescence microscopy as described in Materials and Methods. Bar, 5 μm.

by electron microscopy (Fakan and Bernhard, 1971; Hadjioflov, 1985; Thiry and Thiry-Blaise, 1989; Puvion-Dutilleul et al., 1991; Thiry and Thiry-Blaise, 1991).

**Microinjected MRP RNA Localizes to the Dense Fibrillar Component of the Nucleolus**

To determine if the nucleolar sites of MRP RNA localization indeed correspond to the dense fibrillar component, cells were nucleus-microinjected with rhodamine-labeled MRP RNA, fixed within 1 min after microinjection, and the spatial localization of MRP RNA within the nucleolus was compared with that of fibrillarin, a dense fibrillar component protein (Ochs et al., 1985; Reimer et al., 1987; Scheer and Benavente, 1990) associated with several small nucleolar ribonucleoprotein particles involved in pre-rRNA processing (Tyc and Steitz, 1989). As shown in Fig. 7, rhodamine-labeled MRP RNA (Fig. 7 a; red) and fibrillarin (Fig. 7 b; green) displayed virtually identical patterns in the nucleoli. Superimposition of these two images revealed a very precise colocalization, as indicated by the yellow signal in Fig. 7 c.

**The To Antigen-binding Domain of MRP RNA Is Necessary for Nucleolar Localization**

Sera from certain autoimmune disease patients contain antibodies which recognize a ~40,000-mol wt nuclear protein, the To antigen (Reimer et al., 1988; Kipnis et al., 1990). To antisera also immunoselect a MRP RNA-containing RNP complex (Reddy et al., 1983; Reimer et al., 1988). As can be seen in Fig. 8, the antigenic protein recognized by the original To reference serum (Reddy et al., 1983) is localized predominantly in the nucleoli, with an indication of particular concentration in an array of subnucleolar elements that resemble the dense fibrillar component.

The To antigen binds nucleotides 21-64 of human MRP RNA (Yuan et al., 1991). We therefore examined the importance of this To antigen-binding site in the observed rapid nucleolar localization of nucleus-microinjected MRP RNA. Clones encoding human MRP RNAs were constructed in which nucleotides 23-62 of MRP RNA were deleted or replaced. As shown in Fig. 9 d, deletion of the To-binding site of MRP RNA resulted in a diffuse nucleoplasmic distribution at early times after nuclear microinjection, with no sign of nucleolar localization. Similarly, nuclear microinjection of a mutant MRP RNA in which the To-binding site was altered within the loop regions also resulted in a diffuse pattern throughout the nucleoplasm after microinjection, with no nucleolar localization (Fig. 9 f). Even at later times after microinjection, no nucleolar localization was observed with either of the mutant MRP RNAs (data not shown) pointing to the importance of the To antigen-binding domain.

To determine if other regions of MRP RNA are also necessary for nucleolar localization, we injected into the nucleus a shortened MRP RNA containing only nucleotides 1-79. As shown in Fig. 10, this RNA also became localized in nucleoli. However, the shortened MRP RNA disappeared from the cell altogether within 10–15 min after microinjection (data not shown). While this observation may reflect the dispersion of the 1-79 nucleotide RNA to sites of lower concentration (below the light detection limit of our microscopy system), the initial nucleolar localization of this RNA (Fig. 10) suggests that sequences within nucleotides 1-79 of MRP RNA are sufficient for nucleolar localization.
Discussion

The methods we have developed (Wang et al., 1991, and this paper) for visualizing RNA molecules introduced into living cells can be thought of both as having a "staining" aspect, i.e., affinity of the introduced RNA for immobile intranuclear sites (hence the use of the classical term cytochemistry), but also potentially as a tracer approach for observing dynamic pathways of RNA traffic. We have typically introduced 5,000–10,000 molecules of RNA, each carrying ~5-8 rhodamine groups. The fluorescence signal intensity resulting from a single RNA molecule (between 100-400 nucleotides long) is below the sensitivity of our detection system. When a large proportion of the introduced RNAs accumulate at a relatively small number of intracellular sites, the resulting fluorescent signals are readily detected.

RNase MRP was initially identified as an activity that, in vitro, cleaves mitochondrial transcripts into molecules that can serve as primers for mitochondrial DNA replication (Chang and Clayton, 1987a). When RNase MRP was discovered to be a ribonucleoprotein enzyme and its essential RNA (MRP RNA) component was sequenced (Chang and Clayton, 1987b), it turned out to be identical to a previously defined nucleolar RNA, termed 7-2 RNA (Gold et al., 1989; Yuan et al., 1989). MRP RNA has been detected in mitochondria by in situ hybridization (Li et al., 1994), but the great majority of MRP RNA (7-2 RNA) in the cell fractionates with nucleoli (Reddy et al., 1981). Our demonstration that MRP RNA microinjected into the nucleus rapidly accumulates in nucleoli is entirely consistent with the original localization of MRP RNA (7-2 RNA) as determined by nuclear fractionation.

We have also shown that MRP RNA rapidly accumulates in the dense fibrillar component (DFC) of the nucleolus after nuclear microinjection. As facilitated by fluorescence microscopy, digital optical sectioning, and 3-D stereo visualization (Fig. 6), our images of fluorescent MRP RNA display the DFC at a higher resolution than has been previously achieved in the light microscope. In addition, we have recently carried out in situ hybridization experiments in nontransformed human fibroblasts and in NRK cells and find that the endogenous MRP RNAs in these cell lines are also concentrated in the DFC (Jacobson, M. R., K. Taneja, R. H. Singer, and T. Pederson, unpublished results). Thus, there is also a strong concordance of our fluorescent RNA results with the in situ localization of endogenous nuclear MRP RNA. This local-

Figure 6. Digital optical sectioning microscopy and 3-D reconstruction of nucleolar localized MRP RNA. A through-focus series of optical sections (0.25 μm step size) was obtained of a cell nucleus microinjected with fluorescein-labeled MRP RNA (the same cell observed in Fig. 5 c) as described in Materials and Methods. (A) Serial sequence of optical sections showing the "raw" fluorescence images. (B) The corresponding deconvolved optical sections showing increased apparent resolution and contrast of structures after removal of out of focus light and contrast enhancement. (C) A 3-D stereo pair produced by stacking the set of deconvolved sections and projecting the images angled at +10° and −10° from the optical axis, as described in Materials and Methods. The optical sections are numbered directionally from bottom to top.
Figure 7. MRP RNA rapidly localizes in the dense fibrillar component of the nucleolus after nuclear microinjection. NRK cells were nucleus-microinjected with rhodamine-labeled MRP RNA, fixed ~1 min after microinjection, permeabilized and stained for fibrillarin as described in Materials and Methods. Antibody-antigen complexes were detected with fluorescein-conjugated anti-mouse IgG. (a) Rhodamine-labeled MRP RNA (red); (b) endogenous fibrillarin (green); (c) superimposition of a and b. Bar, 5 μm.

Figure 8. Immunocytochemical localization of the To antigen. NRK cells were fixed, permeabilized, and stained for the To antigen using the original To reference serum (Reddy et al., 1983) as described in Materials and Methods. Antibody-antigen complexes were detected with rhodamine-conjugated anti-human IgG. (a–d) Four representative examples. Bar, 5 μm.
Figure 9. Nucleolar localization of MRP RNA requires the To antigen-binding site. The sequence and secondary structure of the region encompassing the To antigen-binding domain (nucleotides 21–64; Yuan et al., 1991) of wild-type human MRP RNA (a) and mutants MRP-1 (c) and MRP-2 (e) RNAs are indicated. (b) Rhodamine-labeled MRP RNA (wild-type MRP RNA) was visualized in a living cell 5 min after nuclear microinjection. (d) Rhodamine-labeled MRP-1 RNA was visualized in a living cell 2 min after nuclear microinjection. (f) Rhodamine-labeled MRP-2 RNA was visualized in a living cell 4 min after nuclear microinjection. Bar, 5 μm.

A recent fluorescence in situ hybridization study reported that in HeLa cells, a human transformed line, MRP RNA was localized in nucleoli, especially in perinucleolar foci (Matera et al., 1995). We have seen no evidence of such perinucleolar sites of MRP RNA concentration in either our fluorescent RNA cytochemistry work or in situ hybridization experiments, all carried out with nontransformed cells (see also Discussion in Matera et al., 1995). Our results are consistent with the previous nucleolar localization of the To antigen by immunoelectron microscopy (Reimer et al., 1988); we note that the micrographs in this paper revealed most of the gold particles to be located at or near junctions of the granular component with the DFC (see Figs. 3 and 4 in Reimer et al., 1988). As we report here, much of the nucleolar To antigen appears to also be concentrated in a pattern that strongly resembles the DFC as visualized by high resolution fluorescence microscopy (Fig. 8).

Analysis of microinjected mutant RNAs demonstrates that the To antigen-binding domain is necessary for nucleolar localization of MRP RNA. These data suggest that either nucleoplasmic To antigen (see Fig. 8) binds and directly targets MRP RNA to the nucleolus or that nucleolar localized To antigen is a high affinity site for MRP RNA.
accumulation. Although the protein components of enzymatic RNase MRP remain unknown, and as such their role in the nucleolar accumulation of MRP RNA cannot be assessed, rapid nucleolar localization of the “mini-MRP” RNA (nucleotides 1-79) suggests the To antigen-binding domain may be sufficient for nucleolar localization. The site of RNase MRP assembly is also unknown. However, the rapidity with which wild-type MRP RNA (and the mini-MRP RNA) localized in the nucleolar DFC is consistent with it being the site of RNase MRP assembly as well as a site of catalytic activity. Further studies are necessary to more fully elucidate this important point.

How various RNAs that are generated in the nucleoplasm are targeted for the nucleolus is a major unsolved problem in the cell biology of the nucleus. For example, 5S rRNA is transcribed on nucleoplasmic genes and yet associates with the nucleolus (Long and Dawid, 1980). In addition, many newly discovered small nucleolar RNAs (snoRNAs) originate in the introns of nucleoplasmic genes (for a recent review see Maxwell and Fournier, 1995). These traffic patterns are not well understood (although see Steitz et al., 1988). This exciting new aspect of RNA processing and intranuclear traffic awaits identification of the nucleolar targeting signals involved. Our fluorescent RNA cytochemistry method in combination with the molecular mutagenesis of cloned RNAs offers promise for the identification of various RNA domains responsible for nucleolar targeting, as well as for other traffic and localization pathways in the cell.

We thank Tamás Kiss and Witold Filipowicz (Friedrich Miescher-Institut) for plasmid pHMRPMoDT3; Michael Pollard and Eng Tan (Scripps Research Institute) for monoclonal antibody 72B9; Eng Tan (Scripps Research Institute) for the human To reference serum (No. A2106); and Helma Pluk and Walter van Venrooij (University of Nijmegen) for the MRP RNA-RNP monospecific human serum L122. We also thank Roxanne Labrecque for her excellent technical support in this project. We are grateful to Joel Richter and David Wolf (Worcester Foundation) for critically reading the manuscript.
